Abstract
Isolated ureteral strips develop spontaneous phasic contractile activity that is enhanced by 5-hydroxytryptamine (5-HT). The aim of this study was to identify the receptor subtype mediating these responses and to determine whether responses to 5-HT change with age. The frequency of contractions and also the overall contractile activity (measured as the area under the curve, AUC) were recorded in strips of porcine isolated distal ureter from young (3 months) and old (2 years) pigs and responses to 5-HT were examined in the absence and presence of selective 5-HT receptor subtype antagonists. Tissues from the younger animals elicited larger contractile responses to 5-HT (5885 ± 334.8 g s) than tissues from the older animals (5787 ± 334.8 g s, P<0.0001). The 5-HT2A receptor antagonist ketanserin (10-100nM) elicited rightward shifts of 5-HT concentration-response curves, antagonising AUC and frequency responses with high affinity in both age groups (pK_D values 8.4-8.8). The slopes of the corresponding Schild plots were not significantly different from unity, suggesting a competitive antagonism at a single receptor, except for frequency responses to 5-HT in the older animals. Antagonists for other 5-HT receptor subtypes: methiothepin (non-selective), RS-10221 (5-HT2C), ondansetron (5-HT3), GR-113808 (5-HT4), SB699551 (5-HT5), SB399885 (5-HT6), SB269970 (5-HT7)) had no effect on ureteral 5-HT-induced responses. The results suggest that the 5-HT2A receptor subtype is the predominant receptor in all the tissues, being the sole mediator of responses in young animals, but with another receptor subtype also playing a minor role in the older animals.

1. Introduction

5-hydroxytryptamine (5-HT) is found throughout the body and influences smooth muscle activity in various tissues including the intestine, vasculature and urinary bladder (Kim & Camilleri, 2000; Klarskov & Horby-Petersen, 1986; Mohammad-Zadeh, Moses, & Gwaltney-Brant, 2008). The current classification of 5-HT receptors include 5-HT₁ (1A, 1B, 1D, 1E, 1F) which mediate responses via the inhibition of adenylate cyclase; 5-HT₂ (2A, 2B, 2C) which activate phospholipase C; 5-HT₃ which acts as a ligand-gated ion channel and 5-HT₄ which is positively coupled to adenylate cyclase. In addition, there are three additional subtypes that are not so well-defined; 5-HT₅ which inhibit adenylate cyclase and 5-HT₆ and 5-HT₇ receptors that activate adenylate cyclase (Roth, 1994).

While many studies on the ureter have been mainly focused on α-adrenergic and muscarinic as the major sources of contractile stimulation, 5-HT has been shown to also play a significant role. In isolated strips of human ureter, 5-HT induces concentration-dependent contractions (Barnes, 2001; Gidener, Gumustekin, & Kirkali, 1999) that are antagonised by the 5-HT₂ antagonist, ketanserin and the mixed 5-HT₁/5-HT₂ receptor antagonist methysergide, but are not altered by 5-HT₃ and 5-HT₄ receptors antagonists (Gidener, Kirkali, & Guven, 1995). Also, the 5-HT₂A antagonist ritanserin inhibits contraction of the pig isolated intravesical ureter (Hernandez et al., 2003). In addition, the 5-HT₂A agonist 2,5-dimethoxy-4-iodoamphetamine has been reported to increase the frequency of ureteral contractions in pig ureter in vivo in a dose-dependent manner (Hauser et al., 2002).

Ageing has been shown to increase the risk of ureteral calculus development (Hess, 2003) and this could be related to changes in ureteral function, although the effects of age on ureteral responses is unknown. Age-related changes in 5-HT contractile mechanism have been observed in other systems such as the gastrointestinal system (Keating, Nocchi, Yu, Donovan, & Grundy, 2015) and the inhibitory effect of 5-HT₂ receptor stimulation in the rat vas deferens has been found to decrease with increasing age (Moritoki, Iwamoto, Kanaya, Ishida, & Fukuda, 1986). The aim of this study was to identify the receptor subtype mediating ureteral response to 5-HT and to determine whether age has any effect on these responses.
2. Methods and Materials

2.1. Tissue preparation

Fresh bladders with ureters attached were obtained from a local abattoir and immediately immersed in ice-cold Krebs-bicarbonate solution (4°C) composed of NaCl (188.4mM), NaHCO₃ (24.9mM), glucose (11.7mM), CaCl₂ (1.9mM), MgSO₄ (1.2mM) and KH₂PO₄ (1.2mM). Tissues were obtained from 4 month old (young) and 3 year old (old) female pigs. The ureters were detached from the bladders and peri-ureteric fat was removed. The distal ureter was determined as the region 5cm from the entrance to the bladder. The tissues were dissected into 4mm long tissue strip sections. The tissue strips were mounted longitudinally under 1g tension in 8ml organ baths (EZ-baths, Global Towns, CA) containing Krebs-bicarbonate solution, which was maintained at 37°C and continuously gassed with 95% O₂ and 5% CO₂. Isometric tension developed by the tissues was recorded to PC via a Powerlab recording system and Labchart software (ADInstruments, Castle Hill, Australia).

2.2. Contractile responses to 5-HT and α-methyl-5-HT

Complete cumulative concentration-response curves to 5-HT or α-methyl-5-HT (5-HT₂ agonist) were obtained in isolated ureteral tissues from both age groups in the absence and presence of the selective 5-HT₂A receptor antagonist ketanserin (10 – 100nM). Additionally, concentration-response curves to 5-HT were also obtained in the absence and presence of the non-selective 5-HT antagonist methiothepin (10nM), 5-HT₂C antagonist RS-10221 (30nM), 5-HT₃ antagonist ondansetron (30nM), 5-HT₄ antagonist GR-113808 (100nM), 5-HT₅ antagonist SB699551 (10nM), 5-HT₆ antagonist SB399885 (100nM) and 5-HT₇ antagonist SB269970 (10nM). Concentrations producing a selective antagonism for a particular receptor were chosen based on affinity values obtained from the literature.

Only one concentration-response curve was obtained on each tissue. Preparations from the same ureter were compared in each individual experiment, with at least two preparations acting as controls without the addition of any antagonist.

2.3. Data Analysis
Graphpad PRISM software was used for statistical analyses. Mean (±S.E.M.) increases in area under the curve (AUC) relative to weight in grams seconds (g s) and frequency responses in Hertz (Hz) were calculated. Mean (±S.E.M.) maximum responses and –logEC50 (pEC50) values were also recorded for each concentration-response curve. Paired Student’s t-tests were performed on studies with two groups, while two-way ANOVA was used for studies involving more than two groups.

Dissociation constant estimates (apparent pK_B) for antagonists were determined from the equation: pK_B = log (CR-1)-log[B], where CR is the concentration ratio (ratio of the EC50 values) in the absence and presence of the antagonist obtained with a concentration [B] of antagonist. Schild plots were also constructed (Arunlakshana & Schild, 1959) where data from several antagonist concentrations was available.

2.4. Drugs
The following drugs were used: 5-HT hydrochloride (Abcam), α-methyl-5-HT maleate (Tocris), methiothepin mesylate salt (Sigma-Aldrich), ketanserin (+)-tartrate salt (Sigma-Aldrich), RS-102221 (Tocris), ondansetron hydrochloride dehydrate (Sigma-Aldrich), GR-113808 (Tocris), SB 699551 (Sigma-Aldrich), SB-399885 hydrochloride (Sigma-Aldrich) and SB-269970 hydrochloride (Sigma-Aldrich). All drugs were dissolved in distilled water before added to the bathing solution.
3. Results

3.1 The effect of age on 5-HT-induced contractile responses
When subjected to increasing concentrations of 5-HT or the 5-HT₂ selective agonist α-methyl-5HT, all ureteral strips from both age groups developed bursts of phasic contractions and overall contractile activity increased when measured as area under the curve and expressed relative to tissue weight (AUC, g s). Increasing concentrations of 5-HT also resulted in an increase in frequency of phasic activity which was measured in Hz (Fig 1). The potency (pEC₅₀) of 5-HT was similar for tissues from both age groups (Table 2). However, maximal contractile responses measured as AUC were smaller in tissues from the older animals compared to the younger animals (p<0.001, unpaired Student’s t-test, Fig. 1a), while maximum frequency responses were similar in the two age groups (Fig. 1b).

3.2 5-HT- and α-methyl-5-HT-induced contractile responses
Similarly, when subjected to increasing concentrations of the 5-HT₂A selective agonist α-methyl-5-HT, the tissues from both age groups developed bursts of phasic contractions that were measured as AUC and frequency.

3.3 The effect of ketanserin on 5-HT and α-methyl-5-HT induced contractile responses
For both frequency responses and overall contractile (AUC) responses, ketanserin at relatively low concentrations (10 - 100nM) caused significant rightward shifts of 5-HT concentration-response curves in both age groups (Figs 2 and 3). In addition, maximal contractile responses to 5-HT for both AUC and frequency responses appeared to be depressed in the presence of ketanserin (p<0.05, two-way ANOVA, Figs 2 and 3). However, maximum responses could not always be obtained and a comparison of the slopes of the concentration-response curves in each group was performed. There were no statistically significant change in the slopes of any of the curves, suggesting a competitive antagonism. Using EC₄₀ values for responses (expressed as AUC and frequency), Schild analysis was performed on data for tissues from both age groups and pA₂ values (intercept on X-axis) determined (Table 1). Ketanserin had a relatively high affinity for the receptors in this tissue and the slopes of the Schild plots were not significantly different from unity, again suggesting...
a competitive antagonism. The exception was the frequency of phasic contractions in
tissues from older animals, where the slope was significantly steeper than unity (Fig
3b).

Ketanserin (10 - 100nM) also caused rightward shifts of concentration-response
curves to α-methyl-5-HT in tissues from both age groups. Again there was no
significant change in the slope of concentration-response curves to this agonist.
Schild plots again had slopes similar to unity and yielded the pA₂ values (X-axis
intercepts) presented in Table 1.

3.4 The effects of 5-HT receptor antagonists on 5-HT-induced contractile responses
None of the receptor subtype selective 5-HT antagonists RS-102221 (30nM, 5-HT₂C
selective), ondansetron (30nM, 5-HT₃ selective), GR-113808 (100nM, 5-HT₄
selective), SB 699551 (10nM, 5-HT₅ selective), SB 399885 (100nM, 5-HT₆ selective)
or SB 269970 (10nM, 5-HT₇ selective) affected maximal contractile responses or
pEC₅₀ values for 5-HT. Mean pEC50 values and maximum responses for frequency
and AUC responses were similar in the absence and presence of each antagonist
and this was true for tissues from both young and old animals (Table 2).
The non-selective 5-HT receptor antagonist methiothepin (10nM) significantly
reduced responses to 5-HT in ureters from younger animals with both the frequency
responses and the AUC responses being significantly reduced in the presence of
this antagonist (p<0.005, paired Student’s t-test). However this inhibitory effect of
methiothepin was not observed in tissues from the older animals (Fig 4). Additionally
in the tissues from young, but not old animals, methiothepin shifted the 5-HT curves
to the right and significantly reduced pEC₅₀ values for frequency responses to 5HT
(Table 2, Fig 4).
4. Discussion

Previously, it has been demonstrated that 5-HT stimulates contraction of smooth muscle in isolated ureteral strips in a number of species (Gidener et al., 1999; Gidener et al., 1995; Hernandez et al., 2003). In the current study, similarly, 5-HT induced concentration-dependent increases in contractile activity, increasing both the frequency and magnitude of phasic contractions in distal ureters from older and younger pigs. This is in agreement with most other findings in tissues from pig and human (Gidener et al., 1999; Gidener et al., 1995; Hernandez et al., 2003), but contrasts with a study in rabbit isolated tissues that failed to find any ureteral response to 5-HT, suggesting that these responses are species dependent and the pig represents a good model for human (Yalcin et al., 2013).

In our present porcine study, 5-HT produced concentration-dependent increases in overall phasic contractile activity (AUC) and frequency. A similar finding has been reported by Hernandez et al, (2003) for the porcine intravesical ureter. However, in that study, 5-HT preferentially increased contractile tone, but the frequency of these phasic contractions was not related to 5-HT concentration (Hernandez et al., 2003). These authors also found that phasic contractions were abolished during 5-HT-evoked increases in ureteral tone (Hernandez et al., 2003). In our studies no increases in baseline tone were observed upon addition of either 5-HT or α-methyl-5-HT at any concentration. This observed difference can be explained by the difference in ureteral region being studied. The intravesical ureter region utilised in their experiments acts as a sphincter controlling movement of urine into the bladder (Blok, Van Venrooij, Mokhless, & Coolsaet, 1985; Hernandez, Barahona, Bustamante, Garcia-Sacristan, & Orensanz, 1999; Prieto, Hernandez, Rivera, Garcia-Sacristan, & Simonsen, 1997), whilst the distal ureter was examined in the present study. It therefore appears that 5-HT plays different, region specific roles in the urinary tract.

pEC50 values for 5-HT were unaffected by age. Because 5-HT is a full agonist for its receptors, it is unlikely that the decrease in maximal 5-HT-induced contraction with age is due to changes in receptor expression but instead due to altered efficacy of receptor stimulation. It is suggested that the differences in 5-HT-stimulated
contractile responses with age presented here could be due to alterations in the involvement of other receptor subtypes to contractility with age.

In young animals, the 5-HT$_{2A}$ receptor antagonist ketanserin, at relatively low concentrations, shifted 5-HT concentration-response curves rightward, suggesting a role for 5-HT$_{2A}$ receptors in mediating 5-HT-induced contractions of the ureter. The slopes of ketanserin Schild plots for the antagonism of frequency and AUC responses were not significantly different from unity, suggesting that 5-HT$_{2A}$ is the sole receptor subtype responsible for these responses. Furthermore, in these tissues from younger animals, the affinity estimates for ketanserin were comparable to value (8.7) reported at the 5-HT$_{2A}$ receptor in the literature (Bonhaus et al., 1995). Also in tissues from younger animals, there was a slight rightward shift of the 5-HT concentration-response curve in the presence of methiothepin, a generally non-selective 5-HT antagonist, but with an affinity highest at the 5-HT$_{2A}$ receptor subtype (Hoyer et al., 1994). This again suggests the involvement of the 5-HT$_{2A}$ receptor subtype.

This conclusion is further supported by the lack of effect of all the other 5-HT receptor subtype selective antagonists. Based on the affinity values published in the literature, for each antagonist a concentration was chosen that would produce a significant blockade of the specific receptor subtype, without an action at the other receptor subtypes. However none of the antagonists had any effect on concentration-response curves to 5-HT supporting the results obtained with ketanserin and again suggesting that 5HT$_{2A}$ is the only receptor subtype involved in mediating the responses to 5-HT.

In ureteral tissues from older animal, ketanserin again had a relatively high affinity, although a little lower than that obtained in the younger animals. For frequency responses to 5-HT, the Schild plot for ketanserin had a slope that was significantly greater than unity indicating additional antagonistic actions of ketanserin in ureters from the older animals. For this reason the affinity estimate of 7.7 obtained from the intercept of the Schild plot for frequency responses is most likely not reflective of the true affinity value for ketanserin. Additionally, the affinity estimate for AUC responses to 5-HT in tissues from the older animals was lower (8.0) than values in the literature.
and the value obtained in tissues from younger animals. Also, the rightward shift of the 5-HT response curves in the tissues from the younger animals when incubated with methiothepin was not observed in the older animals.

Affinity estimates for ketanserin at 5-HT$_{2A}$ receptors with α-methyl-5-HT stimulation in older animals were also comparable to values (8.7) found in the literature (Bonhaus et al., 1995), indicating that the additional effect of methiothepin is unlikely to be via 5-HT$_{2B}$ or 5-HT$_{2C}$ receptors. This is further supported by the lack of inhibition of 5-HT contractile response by the 5-HT$_{2C}$ selective antagonist, RS-10221. Therefore, it appears that in the younger animals, the 5-HT-induced contractile response is due to stimulation of the 5-HT$_{2A}$ receptor subtype, whilst in the older animals, the 5-HT$_{2A}$ receptor is responsible for the contractile effect of 5-HT and the stimulation of 5-HT on another receptor could cause a relaxatory effect. This is also a possible explanation for the depressed 5-HT contractile responses in tissues from the older animals.

Despite functional studies demonstrating the role of 5-HT in ureteral contractility, the source of endogenous 5-HT in the ureter is unclear. Since 5-HT-containing enterochromaffin cells which are present in the gastrointestinal tract could not be found in the ureter (Nocito et al., 2007; Ripoche, 2011; Theoharides, Bondy, Tsakalos, & Askenase, 1982), it appears that platelets and mast cells might be the source of 5-HT in this tissue. Particularly where intra-ureteral pressure may increase due to the presence of calculi, it is possible that increased vascular permeability secondary to inflammation could result in platelet release of 5-HT in the tissues. Alternatively, mast cells playing a major role in the inflammatory process have been observed in all layers of the porcine ureteral wall under normal conditions (Jerde, Saban, Bjorling, Steinberg, & Nakada, 2000; Vodenicharov, Leiser, Gulubova, & Vlaykova, 2005). Mast cells present in the ureter are most likely involved in maintaining local homeostasis and also play an important role in the regulation of ureteral motility via the release of mediators including histamine and 5-HT in inflammatory circumstances. While our preliminary data failed to find any ureteral response to histamine, it is possible that mast cell regulatory mechanisms occurs via 5-HT. Furthermore, an upregulation of 5-HT$_{2A}$ receptors may occur during obstruction and in the rabbit ureter it has been shown that 5-HT-stimulated
contractile responses are enhanced in the presence of ureteral obstruction (Yalcin et al., 2013).

5. Conclusion
The present data indicate that 5-HT enhances the overall phasic contractile activity of the porcine ureter by increasing both the frequency and magnitude of contractions. With increasing age, overall contractile activity is depressed, but without changes in the frequency responses to 5-HT. The predominant receptor mediating both frequency and contractile responses to 5-HT is the 5-HT2A receptor subtype and this does not appear to change with increasing age. While in vivo experiments are still required, the 5-HT receptor-mediated pathway seems to be upregulated following ureteral obstruction, and therefore, this system could prove to be an effective target for treatment of ureteral calculi. The changes with age that was observed in the present study could also prove to be useful when administering treatment to different age groups.
