Abstract

Introduction

Case study research (CSR) is a research approach that guides holistic investigation of a real phenomenon. This approach may be useful in medical education to provide critical analyses of teaching and learning, and reveal the underlying elements of leadership and innovation. There are variations in the definition, design, and choice of methods, which may diminish the value of CSR as a form of inquiry. This paper reports an analysis of CSR papers in the medical education literature. We aimed to describe how CSR has been used and how more consistency might be achieved to promote understanding and value.

Method

A systematised review was undertaken to quantify the number of CSR articles published in scholarly medical education journals over the last 10 years. We applied a typology of CSR proposed by Thomas and Myers to integrate the various ways CSR is constructed.

Results

Of the 362 full-text articles assessed, 290 were excluded as they did not meet the eligibility criteria; 76 of these were titled 'case study'. Of the 72 included articles, 50 used single-case and 22 multi-case design, 46 connected with theory while 26 were atheoretical. In some articles it was unclear what the subject was, or how the subject was being analysed.

Discussion

In this study more articles titled 'case study' did not meet the eligibility criteria than those that did. Well-structured, clearly written CSR in medical education has the potential to increase understanding of more complex situations, but this review shows there is considerable variation in how it is conducted, potentially limiting utility and translation into educational practice. Case study research may be of more value in medical education if researchers more consistently followed principles of design, and harnessed rich observation with connection of ideas and knowledge to engage the reader in what is most interesting.

Introduction

Case Study Research (CSR) is a form of inquiry that can illuminate interesting qualities and deepen knowledge, ¹⁻⁴ but sometimes what is labelled 'case study' has no foundation in research and may lack purpose, integrity or connection to any analytical frame ³.

Professional fields such as accounting, business, education, marketing, public administration and medicine use CSR. In higher education it is proposed that well-structured, clearly written CSR may be useful in providing critical analyses of underlying issues, identifying and challenging assumptions, and 'guiding intelligent action' ⁵. To teach leadership in innovation to educators of health professionals, Harvard's Macy Institute use CSR about educational reform to reveal interwoven elements of change and circumstance. There is a contrasting view that CSR has no generalizability and therefore lacks scientific value ⁶, and a misperception that 'anything goes' ⁷. Lack of definition, ambiguity about design, disagreement about acceptable methods, and inability to apply findings more generally can diminish the value of CSR as a method of inquiry, contribute to questions about reliability, and limit uptake of research findings ^{3, 6, 8}.

Influential CSR authors generally define CSR as a study of a contemporary, real phenomenon, which involves 'thick description' of a subject, through multiple sources of data or multiple methods ^{1, 2, 4}. 'Contemporary' in this context does not preclude describing events that have already happened, but it distinguishes between history as a 'dead past', and 'contemporary' where research participants have lived experience to impart.

Beyond this definition there is variation in the way CSR is conceptualised. For example, Yin (2014) describes three types of CSR – exploratory, descriptive and explanatory, in a single-case or a multiple-case design. Single-case designs are critical, unusual, revelatory, or longitudinal in relation to the theory or propositions of interest. Within a single case there may be embedded units of analysis, but if there are distinct cases in the one study, then a multiple-case design is adopted ⁴. Stake (2005), is more interpretive, distinguishing between an intrinsic case (where the case is dominant), and an instrumental case (where the issues are dominant); and he termed multiple cases a 'collective case' ².

Bassey (1999) differentiates between a theoretical approach where the aim is to understand or illuminate theory, and an evaluative and/or action approach¹. Incorporating theory is broadly valued to guide data collection and analysis, to add to collective knowledge, or to allow ideas to be viewed differently. Some authors advocate only qualitative methods are used^{2,9}, while others regard the collection and analysis of quantitative data useful when it is relevant to the behaviour and events that the case is trying to explain.

Viewing the whole and acknowledging the complexity of many interacting variables is challenging in research as most scientific inquiry is about breaking things down and seeking understanding of the constituent parts³. The natural sciences enhance study reliability by isolating a few variables in many settings and pursue generalisations through induction. In contrast, CSR explores many variables in a single or few settings as it considers social settings as a synergistic interplay of variables including people and circumstance which are often indivisible³. Ideas are represented and explored, but CSR does not hide from its contextual focus or propose generalization. This worldview is most popular in the social sciences but CSR is not confined to this domain. For example, CSR may be used in public health to investigate outbreaks of disease, with epidemiological statistics used to test possible explanations derived from analysis of interviews and field observation.

The divergence of CSR from other research approaches and its use across traditionally distinct philosophies has contributed to CSR being described as an 'intellectual orphan'³, or existing in a 'methodological limbo'¹⁰. Thomas and Myers provide substantial commentary on the epistemological status of CSR³, and propose that a way toward understanding and acceptance is to distinguish the 'ideographic' of CSR from the 'nomothetic' of other research approaches³. Nomothetic research attempts to establish generalizable principles whereas CSR seeks an ideograph, or a 'picture' of the whole. The epistemological viewpoint and design of CSR will vary depending on the phenomenon to be studied and the researcher's experience and perspective. Accordingly, it is likely the researcher will adopt an approach advocated by CSR exponents who have a similar epistemological stance.

Contemporary proponents of CSR have shifted from valuing a foundation of theory to *phronesis*, a type of wisdom or intelligence relevant to practical things. In this reframing of CSR, the critical contribution of the researcher is to learn from the experience of others in

the field of inquiry, carefully reflect to integrate ideas, and consider the topic from a novel angle¹¹. The study cannot be replicated as each researcher and reader may view the findings differently from a personal perspective; they may each learn something different from it^{3, 5, 8}.

Attributes of good CSR

Case study is a research approach, rather than a uniform methodology. The approach is used to guide holistic investigation of a real phenomenon in order to advance our knowledge of a broader theme. Often social situations are complex and may consist of many interwoven elements that operate in synergy. An assorted set of methods or data sources may align with the research question and the situation to provide depth of understanding, illuminating features that may have otherwise remained latent. To advance beyond purely description, the researcher must analyse what is interesting about the case. Drawing on the experience and wisdom imparted by participants and the researcher's ability to engage coherently with wider theories, emerging ideas are connected to stimulate the readers' conceptual insight and communicate utility^{3, 5, 8, 11}. Stated more clearly, a case study is in no way a sample to be considered representative of a wider population, but a particular representation of a phenomenon which may provide insight into underlying patterns, processes, conditions and mechanisms. The most important attributes are the thought and analysis refracted in a narrative that weaves together questions and discovery, recognition and intuition, challenges assumptions and references the particular³. Proof may not be possible, but the 'imperative of understanding' may be more valuable than proof¹², allowing new research questions embedded in a conceptual framing to be derived from carefully analysed CSR¹³. In this way learning from CSR may be transferred to the reader's own situation⁶.

As there are various ways that CSR is constructed peer-reviewers may have difficulty assessing CSR for publication. To integrate the diverse conceptualisations of CSR, Thomas and Myers (2015) proposed a typology that defines CSR as one of two parts, subject and object³:

- The *subject*, or the case itself, may be a (local) knowledge case, an unusual (outlier) case, or a revealing (key) case.

- The *object* is the analytical frame through which the *subject* is described.

Thomas and Myers (2015) emphasise careful selection of the two parts, arguing it is the alignment between the *subject* (case), as an instance of a class, and the *object*, or way that the *subject* is scrutinised, that is at the heart of robust CSR³. While the *object* may emerge as the inquiry progresses, there is generally an object in mind at the outset. The object incorporates the *purpose*, *approach* and *process* of the case study:

- The *purpose*, or reason for doing the study, integrates Stake's terms 'intrinsic' and 'instrumental'², and 'evaluative' or 'exploratory' used by Bassey¹ and Yin⁴.
- The *approach* establishes a theoretical basis at the outset with an aim to test or build on theory, or the approach may be entirely descriptive (atheoretical).
- The process is either:
 - a single-case study design as one with no comparative analysis, which may be studied *retrospectively* in a defined period of time (*snapshot*), or one which describes change over a period of time (*diachronic*).
 - a multiple-case design incorporates embedded units of analysis within a single-case design (*nested*), one or more comparative analyses occurring at the same time (*parallel*), or where they are happening consecutively and the outcome of one (or the time in between) may affect the other (*sequential*).

While this structure may not be in common use, in integrating the different themes and classifications of CSR, we proposed that it would provide a useful framework for reviewing how CSR is reported in the medical education literature. In this study we undertook a review of how CSR articles have been structured and reported in scholarly medical education journals over the last 10 years. We aimed to describe how CSR has been used and how more consistency might be achieved to promote understanding and value.

Methods

A systematized literature review incorporated a systematic search strategy with a tabulated analysis given that there was no common outcome measurement to synthesise¹⁴. A modified Population, Interest, Context (PICO) review protocol was formulated collaboratively with all authors. As a literature review, ethics approval was not required.

Eligibility criteria

Population

We included in the search all peer-reviewed articles published in scholarly journals from January 2006 to February 2017 that reported primary research of a medical education topic using CSR. This excluded non peer-reviewed articles, books, letters, reports, editorials, perspectives, grey literature; and theses. From the resulting search, we excluded articles where the CSR methods were not discernible, articles where English translation was not available, or where the full text was not available through our library subscriptions.

Interest

CSR was defined as a description of a contemporary event studied in its real-world context, using multiple data sources and/or multiple methods of data collection.

Context

Medical education was defined as a study undertaken at a medical school or other medical training facility including hospitals, or the subject concerned teaching and learning of medical doctors.

Search Strategy

A limited search of PubMed, ERIC, and CINAHL was undertaken using the initial key words “case study”, “medical education”, and additional key words identified from the title and abstract and index terms. A second search was undertaken using all key words identified across PubMed, ERIC, CINAHL, and Informat (Table 1).

Study selection

After automatic and manual removal of duplicate records, one reviewer (CC) screened the title and abstracts of papers against the eligibility criteria, removing non-medical education, non peer-reviewed, and non-case studies. Full-text papers were retrieved for the remaining papers for more detailed analysis against the eligibility criteria.

A random 10% sample of included, and excluded articles that explicitly called the study ‘case study’ was ‘double’ reviewed blind by each of the other authors (RH, PA, JS). That is, three

mutually exclusive 10% samples of included and of excluded articles meant 30% of included and 30% of excluded articles were reviewed twice. The agreement rate of 88.9% was resolved to 100% after discussion but did not result in any additional articles included.

Data abstraction

For each study the author, year, title, and journal, were recorded, and the CSR design according to the typology proposed by Thomas and Myers (2015) was abstracted from the article.

Results

The search strategy identified 1,197 separate articles (Figure 1). Of the 377 articles assessed, 12 were excluded as the full text was not available, and 3 had no readily available English translation. Of the remaining 362 full-text articles, 290 were excluded as they did not meet the eligibility criteria – they did not describe research methods at all, used one data source or one method (eg qualitative interviews at one time-point of one participant group in a ‘single-case study’ design). Of these 290 exclusions, 76 contained ‘case study’ in the article title.

Among the 72 articles included in the review, 10 papers report findings from 4 overarching studies: 3 papers by Rodriguez et al, 1 paper by Lopez-Roig; 2 papers by Van Hoof et al.; 2 papers by Maggio et al; and 2 papers by Preston et al (Appendix 1).

The articles reviewed utilised a CSR approach for a diverse range of topics (Appendix 1). While there was also variety in the design and object of the study, we were able to apply the typology proposed to integrate the range of articles. Most used a single-case design (68%), reported a local case (61%), and were purely exploratory (71%) (Table 2). In spite of the eligibility criteria used to screen articles there remained ambiguity in the design, subject and process. In one article it was not evident whether it was a single or multiple case design. In one article, the object of analysis was determined but neither the subject nor the process were evident. Where the single-case or multiple-case design was unclear it was more difficult to determine how the object was analysed.

The CSR articles in which the structure and design elements were most clearly reported were Skipper et al (2016), Struwig et al (2016), Lund et al (2016), Jippes et al (2013), Isaranuwatthai et al (2014), and Christensen et al (2014).

Discussion

In this review more articles titled 'case study' did not meet the eligibility criteria than articles that did meet the eligibility criteria. Case study research (CSR) is reported in academic medical education journals on diverse topics such as teaching medical microbiology, socially accountable medical schools, successful research education, the impact of culture and context on curriculum change, and the cost effectiveness of simulation. Despite CSR's popularity, we found ambiguity in design, subject, and process.

In medicine, the term 'case study' is variously used: as a mock clinical scenario for teaching purposes; to report an interesting clinical presentation; and to report CSR. While all are acceptable uses of the term, the rules surrounding the construction of a 'case study' in each context may be different, and they may or may not have any foundation in research. For example, an educational case study may be modified to enhance learning, but manipulation of facts in research is prohibited; a case study of a clinical presentation is often a narrative description and may not include research methods, whereas CSR requires intentional design and justified research methods. Further confusion may surround the divergence of a CSR approach from other research approaches. In this review the term 'case study' was sometimes incorrectly used to describe a non-CSR approach in single-site studies and/or small sample sizes. Blurring of the different uses of the term 'case study' may be contributing to CSR being poorly understood and poorly reported.

Quality criteria have been defined for reporting other research approaches, but quality criteria do not appear to be consistently applied to reporting CSR. Academic audiences must feel satisfied with the integrity of the study and that the claims being made are supported by the evidence^{4,5}. Perhaps because of the extent of data collected and the need to limit content to prescribed journal formats, some articles in this study reported findings from only one of the collection methods used. Care needs to be taken that the

holistic nature that is the essence of CSR is not lost in carving out publishable sections. If this is the preferred format for reporting though, it should no longer be described as CSR.

The typology provided a useful framework to understand the structure of the reviewed articles, which were based on various conceptual models. Thomas and Myers warn against being rigidly obsessed with exactitude of design and reliability at the expense of imagination and intuition³. In order to enhance the quality of CSR in academic publications we propose clear description of:

- the contemporary phenomenon (subject) or instance to be studied in its real world setting;
- the analytical frame (object) or aspect of the phenomenon to be explained, including the purpose, approach, and process;
- the single-case or multiple-case design and embedded units of analysis where relevant;
- methods that are congruent with the object; and
- multiple methods or multiple data sources used to achieve rich description, should this be relevant to the purpose and available data.

Consistent and thoughtful construction and a commitment to extract relevant and meaningful information rather than simply writing up a description might promote CSR as a valuable method of inquiry and increase the impact of findings.

Limitations

The number of articles reviewed was limited by the search strategy and eligibility criteria. Only studies published in English were included; while this resulted in only three articles excluded from those selected through the search criteria, articles published in other languages could also have been important to this review. It was not feasible to include books and theses in this review, but there may be value in including a broader range of literature in further research to capture more detailed CSR reports. Nevertheless, we included articles that complied with the accepted definition of CSR and contained sufficient description of methods to allow extrapolation to the framework. While the framework may

not yet be widely used, it may be useful in communicating the key ingredients of good CSR regardless of the epistemological viewpoint of the researcher.

Conclusion

Well-structured, clearly written CSR in medical education has the potential to increase understanding of more complex situations through critical analysis and clarification of contributing factors, challenge to assumptions, and guidance for 'intelligent action' that may have relevance more broadly. A review of CSR in medical education over the last 10 years shows considerable variation in how it is conducted, potentially limiting its value in translation into educational practice. Case study research (CSR) may be of more value in medical education if researchers more consistently followed principles of design and reporting as outlined in this paper. Research frameworks for CSR are available, and their application may reduce ambiguity and enhance the value and transferability of output.
